neous structure: in AL2, the grains of α -solid solution of Si in Al and a large amount of eutectic ($\alpha + \text{Si}$) and in AL9, the α -solid solution and the eutectic $\alpha + \text{Mg}_2\text{Si} + \text{Si}$. Annealing at 290°C for 4 hr reduces by 11-18% the mean ρ of the alloys AL2 and AL9 owing to the relieving of the casting stresses, segregation of impurities into autonomous phases from the supersaturated solid solution, equalization of the chemical composition of the grains and reduction in the number of non-equilibrium vacancies owing to diffusion processes, but, contrary to the expectations it did not result in any marked decrease in the scatter of the values of ρ . Apparently, in Al-Si alloys electric properties fundamentally determine the character of structure. Of the technological factors, only mold temperature seems to have any appreciable effect on the scatter of ρ in the alloys AL2 and AL9. Thus, the alloys AL2 and AL9 may be used as rotor linings only if they do not have to meet rigid requirements as to the stability of the ρ of the "squirrel cage". Pure Al assures a stable ρ (within, +2%) but it is not as strong. Orig. art. has: 3 tables, 2 figures.

ABSTRACT: The interlayer spacings were measured and dislocations were observed in copper phthalocyanin crystals by means of an EM-7 electron microscope in which the resolution was increased to 10 Å. Increasing the excitation of the objective to 4000 ampere-turns considerably decreased astigmatism, and spherical and chromatic aberrations. The electron microscope was used at 60 kV with a diaphragm 30-microns in diameter, at a beam current of 20 microamperes. Magnification

TITLE: Structure of layers of di and triphenylmethane pigments with n and p type conductivity

SOURCE: Fizika tverdogo tela, v. 6, no. 6, 1964, 1907-1908

TOPIC TAGS: diphenylmethane, triphenylmethane, pigment, n type conductivity, p type conductivity, electron microscope, electron diffraction, Siemens Elmiskop I microscope

ABSTRACT: Electron microscope and electron diffraction studies were conducted on reflecting and dispersing layers of brilliant green and crystalline violet diphenylmethane and triphenylmethane pigments to ascertain the forms of their aggregations. The Siemens Elmiskop I electron microscope was used. Reflecting layers were produced by precipitation from ethyl alcohol solution on a charcoal plate. After a 20-30 minute exposure to ethyl alcohol vapors (in air and in vacuum), these layers acquired p-type conductivity. An investigation of photographs and electron-diffraction patterns of reflecting layers not exposed to the vapors proved them to be completely uniform and amorphous. After their
Card 1/2

ACCESSION NR: AP4039692

exposure, the layers were transformed into aggregates of microcrystals 0.05-0.3 μ in size. Their diffraction patterns represented sharply defined rings. It follows that the change in the conductivity from n-type to p-type is intimately related to the structural changes in the solid pigment layers, as was previously proven for metal-free layers of phthalocyanin by V. S. Myl'nikov and Ye. K. Putseyko (FTT, 4, 772, 1962). Orig. art. has: 1 table.

TITLE: Calculation of the internal electric fields and their gradients in perovskite compounds with distinctive dielectric properties [Report, Symposium on Ferromagnetism and Ferroelectricity held in Leningrad 30 May to 5 June 1963]

SOURCE: AN SSSR. Izv.Ser.fiz., v.28, no.4, 1964, 630-635

TOPIC TAGS: internal field , crystal internal field , perovskite structure, ferroelectricity, ionic ferroelectricity model, ferroelectric compound

ABSTRACT: For a number of years the authors have been engaged in calculating the internal electric fields in compounds having the perovskite structure and peculiar dielectric properties. The methods of calculation and the results have been reported in a series of papers appearing in Kristallografiy (Crystallography) and Fizika tverdogo tela (Solid State Physics) from 1958 to 1962. The results of these calculations are discussed in the present paper. The calculations were based on the ionic model of a crystal with known or assumed structure. The charges and polarizabilities of the point ions were treated as given quantities, but the induced dipole moments

Card 1/3

ACCESSION NR: AP4030634

were calculated. Calculations were performed for several values of the charge, polarizability, and radius of the ions; reasonable variations of these parameters did not alter the qualitative picture of the fields in the six compounds investigated (lead, barium, calcium and cadmium titanates, sodium tantalate, and lead zirconate). Good agreement was obtained between observed and calculated values of the spontaneous polarization with the value 0.5 for the ionic charge factor. The results of the calculations indicate that NaTaO_3 and CdTiO_3 are ferrielectric materials and that PbZrO_3 is a ferrielectric material with nearly antiferroelectric properties. The internal field at the position of the Ti ion was found to vanish in CaTiO_3 but to be large in BaTiO_3 and PbTiO_3 . This difference in the fields accounts for the different dielectric behavior of these materials. Because of the strong field at the Ti ion, the conclusion of H.D.Megaw (Acta crystallogr., 5, 739, 1952; Ibid., 7, 187, 1954) that the principal factor in ferroelectric transitions of ABO_3 type materials must be a sharp increase in the covalent character of the B-O bond is regarded as inadequately grounded. It is concluded that further theoretical and experimental investigation of the possibilities of the ionic model is desirable, and improved calculations of field gradients are promised for the near future. TITLE: Investigation of some solid solutions based on the ferroelectric-ferromagnet bismuth ferrite [Report, Symposium on Ferromagnetism and Ferroelectricity held in Leningrad 30 May to 5 June 1963]

SOURCE: AN SSSR. Izv. Ser. fiz., v.28, no.4, 1964, 683-690

TOPIC TAGS: ferromagnetism, ferroelectricity, bismuth ferrite, bismuth ferrite solid solution

ABSTRACT: By investigating solid solutions of $\text{Bi}_2\text{O}_3 \cdot \text{Fe}_2\text{O}_3$ in PbTiO_3 , some of the authors, together with others, were able to show the existence of the compound BiFeO_3 with the perovskite structure and strong ferroelectric properties. This work is reviewed, and later investigations are reported of the electric and magnetic properties of solid solutions containing BiFeO_3 . The solutions discussed are the two-component systems in which one component is BiFeO_3 and the other is LaFeO_3 , LaCrO_3 ,

Card 1/3

ACCESSION NR: AP4030644

PbTiO₃, BaTiO₃, PbZrO₃, LaAlO₃, or SrSnO₃. Of these solutes, two are ferromagnetic, two are ferroelectric, one is antiferroelectric and two are perovskites with normal magnetic and electric properties. Phase diagrams are given for the PbTiO₃, LaCrO₃, and BaTiO₃ solutions. Curves of magnetization versus temperature are given for various compositions of the LaCrO₃ and PbZrO₃ solutions, and curves of dielectric constant versus temperature for the LaAlO₃, PbZrO₃ and BaTiO₃ solutions. The Néel point is plotted against composition for all the solutions except those containing SrSnO₃, which could not be obtained as a single phase. Extrapolation of the Curie points of the LaAlO₃ and PbZrO₃ solutions to zero concentration confirmed the high ferroelectric Curie point (about 350°C) of BiFeO₃. The weak ferromagnetic properties of Bi-FeO₃ persisted in solutions containing high concentrations of materials without peculiar magnetic properties. Particularly interesting is the concentration dependence of the spontaneous magnetization of the LaCrO₃ solutions; the magnetization increased discontinuously as the system crossed the boundary from the ferroelectric to the antiferroelectric state. The LaFeO₃ solutions are said to have behaved similarly, but as these solutions have been discussed in detail elsewhere (Yu.B.Roginskaya, Yu. N.Venevtsev, G.S.Zhdanov and S.A.Fedulov, Kristallografiya, 8, 1963), the data are not given. An anomaly in the Mossbauer spectrum of the SrSnO₃ solutions that was pro-

Card 2/3

TITLE: Concerning the connection between special dielectric and magnetic properties in "ferroelectric magnets"

SOURCE: Zh. eksper. i teor. fiz., v. 46, no. 5, 1964, 1921-1923

TOPIC TAGS: ferroelectricity, ferromagnetism, dipole moment, dielectric constant, specific magnetization, antiferromagnetism, atomic structure, electric structure, magnetic structure

ABSTRACT: To check on the presence of an internal connection between the electric and magnetic dipole structures of BiFeO_3 , which is a new class of substance combining special dielectric and special magnetic properties ("ferroelectric magnets"). Comprehensive investigations were made of the temperature dependences of the unit-cell para-

Card 1/4

ACCESSION NR: AP4037617

meters, the dielectric constant, and the specific magnetization, with special care in the region of the antiferromagnetic transition. The details of the experiment are described. The noticeable anomalies in the curves of these parameters in the region of the Neel point offer evidence of the existence of a connection between the magnetic, electric, and atomic structures. It is precisely by virtue of this connection that the sharp change in the magnetic structure at the point of antiferromagnetic transition leads to noticeable changes in the electric and atomic structures, as reflected in the anomalies of the corresponding parameters near the Neel point. The observation of one of the manifestations of such an interaction in BiFeO_3 , indicates that this connection is experimentally detectable and can be observed and investigated in a comprehensive fashion, by studying the changes in the magnetic and electric characteristics and of the parameters of the atomic lattice as functions of several extraneous factors (temperature, pressure, fields, etc.). The connection can be regarded both on a unit-cell scale, as well as on a scale

TOPIC TAGS: DTA, Rh, Bi, differential thermal analysis, rhodium, bismuth

ABSTRACT: Differential thermal analysis has been carried out for the first time in Rh-Bi equilibrium systems. An equilibrium diagram has been constructed for the above system, starting with pure Bi and ending with a 22.5 weight % of Rh in the eutectic. Rh-Bi thermograms were taken after the alloy had been homogeneously heated for 48 hours at 720°. The only effects shown in the heating curves are the ones corresponding to the eutectic transformation, reaction of RhBi_2 formation, and the solid solution transformation $\alpha \rightarrow \text{RhBi}_2$. The differential effect corresponding to the eutectic transformation disappears completely when the

parameters were determined by a method previously described (Narita, *J. Laboratory*, **27**, 1117, 1971). The x-ray phase analysis of the solid in the first rubis solid solution over the entire composition range was performed by the LaF₃-LaCl₃ method. The semiquantitative analysis of the solid solution in the solid solution was performed by the method of the ratio of the intensities of pseudomorph reflections, M₁, M₂, and M₃. The x-ray patterns of the 73-100 mol.-% LaCl₃ range, recorded at 100°C, show a sharp discontinuity in the parameters of the reflections. The discontinuities, together with a decrease in volume of the unit cell, indicate that there is a new stage of the transformation of the solid solution. voltmeter.¹¹ The maximum conductivity was found for compositions between 10% LaFeO₃. One of the two breaks on each of the curves of σ versus temperature coincided with the Neel temperature T_N . The general behavior of σ versus temperature, together with the x-ray data, indicates that the dielectric properties of samples in the 2%—10% LaFeO₃ composition range, which contain less than 45% LaFeO₃, increases continuously with increasing temperature. It is concluded that the rhombohedral modification is ferroelectric at low temperatures, and ferroelectric because of the presence of magnetic moments. The existence of the rhombohedral region of the BiFeO₃-LaFeO₃ system, although it appears to be absent in that region in the system studied, was established by the diagram shown in Fig. 1, was established on the basis of the following facts. The fine line represents the ferroelectric Curie point as a function of composition. Two regions of the diagram are of particular interest, that of compositions up to 18.8 mol% LaFeO₃, which combine ferroelectricity with strong paramagnetic properties, and that of compositions in the 18.8%—100% range, represented by the anti-ferroelectric with weak ferromagnetic properties. Discontinuity of the transition between the two regions with the discontinuity of T_N is considered proof of a definite interconnection between the special electrical and magnetic properties.

TITLE: The coexistence of antiferromagnetic and ferromagnetic properties in the system BiFeO_3 - LaFeO_3

PUBLICATION: Zhurnal eksperimental'noi i teor. fiz., v. 44, no. 4, 1963, p. 1416-1422.

TEXT: The system BiFeO_3 - LaFeO_3 was investigated in the range 120-1400°C in two compositions. The first composition contained 10% LaFeO_3 and the second 20%. X-ray diffraction analysis showed that the samples had a perovskite structure. The magnetic properties were studied by the method of thermomagnetic measurements. The magnetic susceptibility was measured from 10° to 800°K and in the temperature range 1000° to 1400°C. The magnetic moments of 10.0% LaFeO_3 and all perovskite samples were found to be zero. Crystal structure of dibromanthraquinone

PERIODICAL: Kristallografiya, v. 3, no. 2, 1958, p. 333

TEXT: Single crystals of 1,5-dibromanthraquinone $(C_7H_3O)_2Br_2$ in the form of long dark-yellow needles were obtained by slow evaporation from a solution in pyridine and also by sublimation in a normal atmosphere. The parameters of the monoclinic unit cell were found by X-ray measurements to be $a = 11.24 \pm 0.02$, $b = 13.43 \pm 0.03$, $c = 3.93 \pm 0.01$ Å, $\beta = 91^\circ 23' \pm 12'$, $V = 598 \text{ \AA}^3$. The density was calculated from the data to be 2.03 g/cm^3 which is close to the value obtained from pyknometric measurements (2.02). The number of molecules in the unit cell is two, and the space group is

$C_{2h}^5 - F\bar{2}_1/a$. The deviation of the bromine and oxygen atoms on different sides of the plane of the anthraquinone ring was found to be +0.158 and -0.136 Å respectively. The bond length of

TITLE: Electron microscope observation of the formation and growth of ice crystals
Report, Fifth All-Union Conference on Electron Microscopy held in Sumy 6-8 July 1965

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 5, 1966, 835-839

TOPIC TAGS: electron microscopy, crystal growth, ice, water, electric field

ABSTRACT: The growth of ice crystals on cold thin carbon and quartz films was observed with an electron microscope. The ice crystals formed by condensation of residual water vapor which was present in the microscope chamber at pressures ranging from 10^{-5} to 10^{-3} mm Hg. The accelerating potential was 80 kV, the electron beam diameter was 5-10 microns, and the current density in the beam was 0.01 A/cm^2 . Under these conditions heating of the substrate by the electron beam was negligible. Hexagonal, cubic, and amorphous forms of ice were observed. The hexagonal form was stable over a wide range of temperatures; the cubic form could be obtained free from hexagonal admixture only at high vacuum and temperatures below 145° K . A sharp change in the character of the crystallization took place at 170° K ; instead of the formation of large crystals, there was observed the almost simultaneous appearance of a large number of nuclei which

Card 1/2

45
44
B

L 36337-66

ACC NR: APG015778

grew preferentially in the plane of the substrate. On the quartz substrates there were observed filamentary ico structures, which grew rapidly toward the irradiated portion of the film. These structures are ascribed to the action of electric fields due to charging of the quartz substrate by the electron beam. From a comparison of the present observations with those of J.T.Bartlott, A.P.van den Heuval, and B.J. Mason (Z. angew. Math. und Phys., 14, 599 (1963)), it is concluded that the electric field strength exceeded 500 V/cm. The polycrystalline nature of the filamentary structures was clearly evinced on the electron micrographs. The authors thank L.V. Degtova for assistance in preparing the substrates. TOPIC TAGS: superconducting alloy, Mössbauer effect, chemical bonding, tin,
isomorphism, hyperfine structure

ABSTRACT: A survey is made of the various applications of the Mössbauer effect to the study of superconducting alloys. The method of determining the type of chemical bond is discussed by using the isomorphic shift of Mössbauer lines, or

$$\delta = E_s - E_e \sim A [R_u - R_e] [|\Psi_s(0)|^2 - |\Psi_e(0)|^2].$$

For white tin the $|\Psi_s(0)|^2$ versus δ curve is used to obtain the effective number of s-electrons, quantitatively. Then, utilizing the fact that superconductivity is connected with phonon-electron interactions in a crystal, the Mössbauer effect is used to determine f where

$$f(0, T) = \exp \left(-\frac{E_0^2}{2M\epsilon^2} \cdot \frac{3}{2kT} \right).$$

Card 1/2

L 38541-66

ACC NR. AT6014763

3

If f is determined experimentally for a metal in both normal and superconducting states, the Debye temperatures before and after transition can be directly compared. This, however, is shown to be a very sensitive experiment and is very difficult to perform. Finally, the possibility is investigated for using the Mössbauer effect to serve as a low-temperature/thermometer. This could be done by observing the splitting of the Fe^{57} ground level into two sublevels for which a unique temperature can be determined. Once more, it is stressed that because of small magnetic moments the phenomenon of splitting is small and the experiment very sensitive to noise. Orig. art. has: 6 figures and 3 formulas.

TITLE: The use of zeolites for decreasing hydrocarbon accumulation in electron microscopes

SOURCE: AN SSSR, Doklady, v. 163, no. 4, 1965, 865-867

TOPIC TAGS: zeolite, electron microscope, hydrocarbon, contamination

ABSTRACT: Present measures for prevention of contamination in electron microscopes are deficient chiefly because of the difficulty of introducing the cooled protective diaphragm into such a narrow space--the restricted zone of the upper pole piece of the objective lens. The authors suggest a method of decreasing the partial hydrocarbon pressure in the electron microscope by means of zeolites. The zeolites were chosen because of their great adsorbent properties at low pressures, their high mechanical strength, and the simplicity of their regeneration. Zeolite granules were introduced directly into the tube of the instrument or in a glass extension attached to the tube. Even without cooling, this arrangement proved very effective. Zeolite granules with pore spaces of 10 Å and specific surface of 1000 m²/g were used. The rate of hydrocarbon accumulation was observed at a

Card 1/2

L 2374-66

ACCESSION NR: AP5020826

current density of 0.2-0.5 amp/cm² and a beam density of 3-4 μ . The initial rate of growth was 2 $\text{\AA}/\text{sec}$. Several days after adding the attachment with zeolites, the rate had declined to 0.25-0.2 $\text{\AA}/\text{sec}$. Introduction of zeolite in a ring directly around the specimen caused the rate of growth to decline to 0.08-0.04 $\text{\AA}/\text{sec}$. When the beam was especially intense, the organic film could be removed entirely. It was found that zeolites give practically the same results as a cooled chamber, and the technique eliminates the existing difficulties of manipulation as well as the necessity of using liquid nitrogen. Zeolites may also be used for devices other than the electron microscope when such problems of contamination are encountered. "The authors express their thanks to S. P. Zhdanov for fruitful consultations during the work." Orig. art. has: 3 figures.

TITLE: Study of the structure and magnetic and electric properties of solid solutions in the system BiFeO_3 - " $\text{Sr}(\text{Sn}_{1/3}\text{Mn}_{2/3})\text{O}_3$ "

SOURCE: Kristallografiya, v. 10, no. 5, 1965, 644-649

TOPIC TAGS: solid solution, Neel temperature, Curie point, antiferromagnetic material, spontaneous magnetization, bismuth compound, iron compound, strontium compound, tin compound, manganese compound

ABSTRACT: The samples were prepared by the usual ceramic process from Bi_2O_3 , SnO_2 , SrCO_3 , Fe_2O_3 , and MnO_2 (firing at 75 - 1100°C at 4 - 6 hr and again at 820 - 1600°C for 1 - 2 hr). After each firing, the phase composition of the samples was checked by x-ray diffraction. The latter showed that the system BiFeO_3 - $\text{Sr}(\text{Sn}_{1/3}\text{Mn}_{2/3})\text{O}_3$ contains a broad single-phase region of solid solutions based on the composition $\text{Bi}_2\text{O}_3 \cdot \text{SnO}_2 \cdot \text{SrCO}_3 \cdot (\text{MnO}_2 \cdot \text{Fe}_2\text{O}_3)^{1/3} \cdot \text{Sn}(\text{Mn}, \text{Fe})_{2/3}\text{O}_3$. Analysis of the splitting of the principal cell parameters of the samples in the system BiFeO_3 - $\text{Sr}(\text{Sn}_{1/3}\text{Mn}_{2/3})\text{O}_3$ shows that the solid solutions in this system exist in four modifications: rhombohedral, cubic, pseudocubic, and monoclinic II. The Neel temperatures T_N of the various samples were determined from the temperature dependence of spontaneous magnetization. Below T_N , the solid solutions are antiferromagnetic with a weak ferromagnetism. It was found that in the system studied there is a wide region of

Card 1/2

U-263-66

ACC NR: AP5024548

2

solid solutions in which a magnetic and an electric dipole structure exist over a wide temperature range. No distinct correlation was noted between these structures, and no special effort is made to elucidate it. "We thank Yu. Ye. Roginskly for valuable suggestions and comments." TITLE: The Mossbauer effect in compounds of the fluorite type (IrSn₂ and PtSn₂)

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 5, 1965,
1389-1393

TOPIC TAGS: Mossbauer effect, platinum compound, iridium compound, temperature dependence, resonance absorption, Gamma ray absorption, absorption probability

ABSTRACT: This is a continuation of earlier work by one of the authors (Kuz'min, with V. A. Bryukhanov and N. N. Delyagin, ZhETF v. 46, 137, 1964) on the Mossbauer effect in compounds of the fluorite type. The purpose of the present investigation was to study, for a given type of crystal lattice, the effect of changing the surroundings of the Mossbauer atom, the mass of the atom, and the structure of the 4-band. The IrSn₂ and PtSn₂ compounds were obtained by melting the components in quartz ampoules and subsequent annealing. The absorbers were prepared by pressing powders of the compounds in mixture with beryllium oxide. The resonance absorption of 23.8-kev gamma quanta by Sn¹¹⁹ nuclei was investigated in the temperature range from 77 to 600K.

Card 1/2

L 13130-66

ACC NR: AP6000189

The results showed a decrease in the resonance absorption with increasing temperature, similar to that previously observed for Mg_2Sn . The probabilities for recoilless resonance absorption of the γ quanta and the widths of the absorption lines were determined for both compounds (Table). The results are interpreted on the basis of data concerning the structure and the nature of the chemical bond in these compounds. Tests were also made with $IrSn_2-PtSn_2$ alloys with 25, 50, and 70 mol.% $PtSn_2$. All three alloys gave single Mossbauer lines. Orig. art. has: 2 figures and 1 table.

TITLE:	The Mossbauer effect in the intermetallic compounds Co _{1.4} Sn and Ni _{1.4} Sn /Report All-Union Conference on the Physics of Ferro-and Antiferromagnetism held 2-7 July 1965 in Sverdlovsk/	Report	
SOURCE:	AN SSSR, Izvestiya. Seriya fizicheskaya, v. 30, no. 6, 1966, 957-961		
TOPIC TAGS:	Mossbauer spectrum, Mossbauer effect, magnetic susceptibility, cobalt alloy, nickel alloy, intermetallic compound		
ABSTRACT:	The present study was undertaken in conjunction with the growing interest in nuclear resonance absorption in intermetallic compounds, in particular those containing ferromagnetic elements. Specifically, there was studied the Mossbauer effect in Co _{1.4} Sn and Ni _{1.4} Sn. The compound specimens were prepared by vacuum melting of the components, followed by homogenizing anneal in sealed tubes (50 hours at about 800°C) and then slow cooling to room temperature. In the same manner there were prepared specimens of mixtures of the two above-mentioned compounds, i.e., representatives of the Co-Ni-Sn system. Among the last only samples with the NiAs structure were selected for the Mossbauer measurements. The Mossbauer effect was studied on the Sn ¹¹⁹ nuclei

in specimens with a "tin" thickness of 9 mg/cm². The source of the 23.8 keV gamma rays was a 5 mg/cm² thick sample of Mg₂Sn. The measurements were performed with the source at liquid nitrogen temperature. The Mossbauer spectra obtained for Co_{1.4}Sn at different temperatures of the absorber and for a series of Co_{1.4}Sn-Ni_{1.4}Sn solid solutions (0,9,25,50 and 100% Co_{1.4}Sn) are reproduced in figures. Also presented in graphics are the temperature dependences of the reciprocal susceptibility as obtained by the authors and taken from the literature (M. Asanuma, J. Phys. Japan, 17, 300, 1962); the agreement for Co_{1.4}Sn is better than for Ni_{1.4}Sn. The temperature variation of the Mossbauer spectra shows that quadrupole splitting persists up to the temperature of the phase transition, that is, up to the temperature of the break in the reciprocal susceptibility versus temperature curve; above the transition point there is observed only the singlet Mossbauer line. The results are discussed briefly and reasons are hypothesized for the absence of ferromagnetism in the studied intermetallic compounds. Further investigations must be made before a full interpretation of the present results can be offered. Orig. art. has: 4 figures.

TITLE: Scattering of Mossbauer radiation by crystals

SOURCE: Kristallografiya, v. 11, no. 4, 1966, 511-519

TOPIC TAGS: Mossbauer effect, gamma scattering, atomic structure, crystal
structure analysis

ABSTRACT: The authors present a theoretical analysis of the application of the
Mossbauer effect, and especially resonant scattering of quanta by nuclei of atoms
in a crystal, to the investigation of the atomic structure of crystals. The theory
of the method is reviewed and it is shown how measurement of a sufficiently large
number of reflections makes it possible to establish the crystallographic planes
which contain Mossbauer atoms. The experimental data which can serve as a basis of
structural analysis by the Mossbauer-atom method are reviewed. It is shown that the
Mossbauer method combines the advantages of other structure-analysis methods and in
addition has a greater flexibility. It also permits an analysis of complicated

biological crystalline objects. Although there are still many experimental difficulties, it is concluded that there are grounds for assuming Mossbauor scattering and diffraction to take their place among other diffraction methods of structural analysis. Orig. art. has: 4 figures and 18 formulas.

Title : Effect of Timing Sowings, and Norm for Oat Yield in Kulundin Steppe.
Orig Pub : S. kh. Sibiri, 1956, No 6, 41-45

Abstract : In field experiments of the Slavgorodsky specimen section of Altai region (1941-1949) and according to data of other experimental institutions in the steppe districts of Western Siberia and Northern Kazakhstan, it was established that the sowing of oats in the third 10-day period of May increases the yield on the average from 14.5 to 17.7 centners/hectare, shortens the vegetative period, and increases the absolute weight of grain. The best norm for sowings is 3 million germinating seeds per hectare.

Orig Pub : Zemledeliye, 1957, No 2, 18-22.

Abstract : In the rayons of Kulundinskiy steppe, the yield of oats could be considerably increased by the following measures: sowing towards the end of May; replacement of the rayoned seed variety Pobeda by seeds of the variety Omakiy 6922 which are less glumaceous by some 4 to 5% and have a vegetative period shorter by 3 to 5 days than the variety Pobeda; sowing norm: 3 million seeds per hectare.-- Yu. TITLE: New Porcelain Low-Voltage Grain Filler Fuse Cutouts
(Novyye farforovyye nizkovol'tnyye nasypnyye predokhraniteli)

PERIODICAL: V sb.: Raboty M-va elektrotekhn. prom-sti SSSR po mekhaniz. i
avtomatiz. nar. kh-va, Z. M., 1956, pp 164-166

ABSTRACT: A description, a picture, and a mounting sketch with dimensions are presented of a new line of low-voltage porcelain grain-filler fuse cutouts, PN2, series, manufactured by Kursk Factory of Low-Voltage Equipment for rated currents of 100, 250, 400, and 600 amp. The new fuse cutouts are intended for AC standard-frequency installations up to 500 v, and differ from the older PNR line of the same factory in their smaller size, in porcelain-tube construction, contact blades, and fusible links, and also in their higher interrupting rating. The new cutout weighs 27.6-41.8% less than the older type, depending on the current rating. Also, it requires less steel and copper than the

Card 1/2

SOV/112-58-1-500

New Porcelain Low-Voltage Grain-Filler Fuse Cutouts

older one. Unlike conventional round cross-section porcelain tubes, the new cutout has a square cross-section tube. Under test conditions, the new cutouts repeatedly interrupted 3-phase currents of 300-27,000 amp rms at 440 v, at power factor 0.12-0.2. The new cutout has a detachable handle for replacing fuse units.
